# A SCORING SYSTEM FOR PERFORMING EPISIOTOMY

#### Asis Kumar Chatterjee,

## SUMMARY

A clinical scoring system for selection of cases for episiotomy was devised by the author & a study conducted in DSP Hospital. This depends on 8 clinical criteria viz: (1) Parity; (2) Maternal Age; (3) Duration of gestation; (4) Estimated fetal size; (5) Rigidity of perineum; (6) Frequency of uterine contraction; (7) Duration of uterine contraction & (8) Hardness of fetal head. Each criterion carries a point of 0 to 2. Total points (= score) of any patient is calculated (0 - 14). Episiotomy performed upto a score of 8 & no episiotomy if the score is more than 8(9-14). Total 86 cases were studied & compared with a control group of another 86 cases with similar parity-wise distribution. Results show that in all the 3 parity groups (Gr A = Primi, P O; Gr B = Multi P1-4; & Gr C = Grande Multi, P5 & above) the number of episiotomies performed is LESS in the study group to a significant number. Maternal injuries were similar in the study & control groups. No fetal injury detected in either group.

Inference drawn is that this simple clinical scoring system has a definite value in reducing the number of episiotomies.

#### **INTRODUCTION:**

In all hospitals, it is customary that almost, if not all, primi gravidas & a large number of multigravidas are delivered by giving an episiotomy. However, there is no rule as to when to perform an episiotomy. Though there are several papers in the literature on the method(s), outcome & long term effect of episiotomy, there is

Dept. of Obst. & Gyn. Durgapur Steel Plant. Durgapur.

Accepted for Publication on 17/6/91

no definite rule regarding the case selection. To overcome this, a clinical scoring system devised by the author was applied in 86 cases in DSP Hospital. This paper is a preliminary report on this scoring system.

#### **MATERIAL & METHOD**

In total 86 cases (all normal vaginal deliveries) were selected. Of these, 36 were primi, 30 between P1 to P4 & 20 P5 & above. the scoring system was applied on these. Side by side, as a control, 86 cases were taken (with similar distri-

THE SCORING SYSTEM

bution parity-wise), where the scoring system was not applied.

The outcome was studied & compared in two groups on the following points:

- 1) Total number of episiotomy done.
- 2) Maternal injury (i) Vaginal & Paraurethral tears (ii) C.P.T.
- 3) Fetal Injury

# THE SCORING SYSTEMS

# The clinical scoring system, depends on 8 criteria & points (SCORE) were allotted to them as below.

Episiotomy was done where the score is 0-8 No. episiotomy was done if the score is more than 8.

| 1. | Parity                                | Primi (P O)       | P2-P4              | P5 & above        |
|----|---------------------------------------|-------------------|--------------------|-------------------|
|    | Score                                 | 0                 | 1                  | 2                 |
| 2. | Maternal age                          | Less than 18 yrs  | 18-30 yrs          | More than 30 yrs  |
|    | Score                                 | 0                 | 2                  | 1                 |
| 3. | Duration of gestation                 | Less than         | 37-41 wks          | More than         |
|    | and since it's Magdaley of period and | 37 wks.           |                    | 41 wks            |
|    | Score                                 | 0                 | (T) the 1 sections | 0                 |
| 4. | Estimated fetal                       | Less than average | Average            | Larger than       |
|    | Size/weight                           | average           | (2.5 - 3.0 kg)     | average (above    |
|    |                                       | (below 2.5 kg)    |                    | 3.0 kg)           |
|    | Score                                 | 2                 | in a second        | 0                 |
| 5. | Laxity of introitus of                | Tight introitus   | Medium             | Lax introitus     |
|    | Rigidity of Perineum                  | Rigid perineum    |                    | & soft perineum   |
|    | Score                                 | 0                 | 1.                 | . 2               |

|    | Score                                 | 0                 | 1                  | 0                 |

No episiotomy = 9-14

498

#### A SCORING SYSTEM FOR PERFORIMG EPISIOTOMY

#### RESULTS

#### A. Total number of episiotomies done :

In control group all primis & many multigravidas were subjected to episiotomy.

In study group, the number of episiotomies in any given group were less than the control group (Table I).

**B.** Maternal Injuries:

The incidence of maternal injuries were not increased significantly in the study groups

## C. Fetal Injuries:

No fetal injury was found in either group.

#### **DISCUSSION:**

1. From Table I it is seen that the number of patients saved from unnecessary episiotomies in the study group is 13 primi, 6 multi & 1 grande multi.

This is highly significant.

#### TABLE I

| Patient               | Group   | No. of cases | Episiotomy done<br>(% age) |
|-----------------------|---------|--------------|----------------------------|
| Primi                 | Study   | 36           | 23 (64%)                   |
| (PO)                  | Control | 36           | 36 (100%)                  |
| Multi                 | Study   | 30           | 12 (40%)                   |
| (P1 -P4)              | Control | 30           | 18 (60%)                   |
| Grande                | Study   | 20           | Nil (0%)                   |
| Multi<br>(P5 & above) | Control | 20           | 1 (5%)                     |

#### Total number of episiotomy done:

\*\* P.U. Tear = Para Urethyal tears

**CPT = Complete Perineal tear** 

# TABLE III

| Patients | P.U.    | C.P.T.                |                  |      |   |
|----------|---------|-----------------------|------------------|------|---|
|          | Group   | No. of<br>Total cases | Perineal<br>Tear | Tear |   |
| Primi    | Study   | 36                    | 4                | 1    | 0 |
|          | Control | 36                    | 0                | 3    | 0 |
| Multi ·  | Study   | 30                    | 2                | 0    | 0 |
| •        | Control | 30                    | 3                | 1    | 0 |
| Grande   | Study   | 20                    | 1                | 0    | 0 |
| Multi    | Control | 20                    | 4                | 2    | 0 |

 From Table II & III it is evident that maternal injuries were not increased in the study group when compared to the control group.

- Among those patients who were not subjected to episiotomy depending on the scoring system, the incidence of maternal injuries was not significant.
- 4. There was no fetal injury in either group.

#### **CONCLUSION:**

This scoring system is purely clinical requiring no special gadgete. It can be applied anywhere & can be practised by any obsterician or even midwives. It is very simple & costs nothing.

Yet, this can save a significant number of mothers from unnecessary episiotomies with potential short & long term ill-effects.

Hitherto there were no scientific criteria to select cases for episiotomy. This is an attempt on scientific basis and it deserves at trial by others.

# **ACKNOWLEDGEMENT** :

The author thank Dr. S. Sengupta, Head of the Deptt. of Gyn. & Obstt., for his encouragement to conduct the study & Dr. R.P. DIXIT, Sr. Dy. Director, M & H Services, D.S.P. for his kind permission to publish this paper.
