An interesting case of pregnancy associated with Carcinoma breast with bilateral ovarian metastasis, the conception having occured during the course of treatment for Carcinoma breast is being reported because of its rarity.

Mrs. S., 34 yrs., third gravida with no living child came to us in June'94 with amenorrhoea of 4.1/2 months. LMP: 18.01.94. Patient was referred from a local private nursing home where she had gone for termination of pregnancy since she was being treated for Carcinoma breast. Patient had undergone right sided mastectomy with axillary clearance a year back in March'93 for a lump in the right breast diagnosed as infiltrating duct Carcinoma. Post operatively patient had taken chemotherapy for 2 cycles the drugs used being cyclophosphomide, 5 FU, and Methotrexate. Patient also had radiotherapy for 10 days i.e. from 20th to 30th Janaury'94, within 2 days of her LMP. During the course of pregnancy at 4th month patient developed pain and loss of power in the right upper limb for which she was advised termination of pregnancy. Clinically the size of the uterus was 20 wks at the time of attempted teermination. Patient was induced with primiprost tablets and injection prostodin was also used after previous insertion of laminaria tent. As there was no response she was shifted to M.S. Ramaiah Hospital. Her obstetric parity index was $G_3P_1A_1D_1$. LMP : 18.01.94.

Clinical examination revealed a conscious patient who was obese, no pallor, a linear scar present on right side of chest, there was edema of right upper limb with grade 0 power in the same limb.
